OAG password rules

* The password must be at least seven characters long and cannot exceed fifty characters.
* The password is case sensitive and must include at least one letter and one numeric digit.
* The password may include punctuation characters but cannot contain spaces or single or double apostrophes.
* The password must be in Roman characters.
World of Warcraft
Wizard Rules

* Your Account Password must contain at least one numeric character and one alphabetic character.
* It must differ from your Account Name.
* It must be between eight and sixteen characters in length.
* It may only contain alphanumeric characters and punctuation such as A-Z, 0-9, or !"#$%. 
United Airlines rules

Passwords may be any combination of six (6) characters and are case insensitive.

Your password will grant you access to united.com, as well as other United features such as our wireless flight paging service, EasyAccess.

For security, certain passwords, such as "united" and "password" are not allowed.

Passwords are case insensitive; please remember how it is entered
Minimum password length is six (6) characters and must include characters from at least two (2) of these groups: alpha, number, and special characters.
New Password: ************
Verify Password: ************
Secret Question: – Select Secret Question –
Secret Question Answer: 

* New Password must be minimum 7 alpha/numeric characters.
* New Password must contain at least 1 numeric symbol.
* Answer to Secret Question needs to be from 2 to 32 characters.
Passphrase Rules:

It must be a minimum of 4 words separated by blanks, at least 1 word must be 5 characters or longer.

It is case sensitive and cannot be less than 11 characters or more than 50 characters long including blanks.

It cannot contain single quotes, double quotes or ascii newline characters.

It cannot contain 3 or more consecutive identical characters.

You may NOT reuse any of the last 6 previously used passphrases.
• The password may not contain your user name.
• The password must contain a minimum of six characters although eight characters are recommended since future complexity parameters will require an eight-character minimum.
• The password must contain three of the following characteristics:
  ◦ Uppercase alphabet characters (AZ)
  ◦ Lowercase alphabet characters (az)
  ◦ Arabic numerals (09)
  ◦ Non-alphanumeric characters (for example, !,$,#,%)

Tuesday, November 3, 2009
- Passwords shall not contain any proper noun or the name of any person, pet, child, or fictional character. Passwords shall not contain any employee serial number, Social Security number, birth date, phone number, or any information that could be readily guessed about the creator of the password.
- Passwords shall not contain any simple pattern of letters or numbers, such as "qwerty" or "xyz123".
- Passwords shall not be any word, noun, or name spelled backwards or appended with a single digit or with a two-digit "year" string, such as 98xyz123.
- Pass phrases, if used in addition to or instead of passwords, should follow the same guidelines.
- Passwords shall not be the same as the User ID.

Create a password between 8 to 15 characters. Your password must contain at least:

- one special character (shift-number)
- one uppercase character
- one lowercase character
- and NOT contain any spaces
Also....

• Use a Different Password on each target system

• Change your password frequently

• Don’t Reuse Passwords

• Don’t write your password down
Who is Responsible For This Eye-Of-Newt Password Fascism?
Well I am a Little
What are these rules for?
Dictionary Attacks

How many times can I try to guess your password?
How Many Guesses?

History of passwords

- A: a lot
- A: jillions
- A: zillions (>> jillions)
- A: three
- A: three, and the correct answer changes each time you try
A: A lot of guesses

- Late 1970s, when Unix passwords were hashed with a salt (Morris and Thompson)
- That made pre-computation impractical
- Access is mostly timesharing
A: Jillions

- Moore’s Law carries on, people don’t pick better passwords
- Networked services offer access to password files on misconfigured sites
- WAYWYT?
A: Today: Zillions

- Clouds, botnets, screen savers are all perfect for dictionary attacks
- If brute force doesn’t work, use more.
The Dictionary Attack Arms Race

- Moore’s Law: 12 doublings since 1990
- And multi-core CPUs are perfect for password cracking
- Can a human choose and remember a password that a computer can’t guess when limited only by computer speed and time available?
Evolution of the bad guys

- academics
- teens without girl friends
- governments
- organized crime, drug lords, terrorists
We Knew People Pick Weak PWs by 1990

It is simply poor engineering to expect people to select and remember passwords that are resistant to dictionary attacks
Results

• People violate many of these rules routinely, for usability reasons

• Stringent rules increase use of fall-back systems, which are usually less secure, or more expensive

• The rules don’t make most things more secure in the face of most current threats
A: Three guesses

• Lock the account for a while or forever if there are too many wrong guesses in a row, or too many wrong guesses forever

• A locked account is a pain, but much better than illicit access

• Any non-moronic password can now be used
Non-moronic password rule

• Pick something a friend, colleague won’t guess in a few tries.
Summary solution

• Limited guesses and lock the account
• Non-moronic passwords
The threat model has changed!

- Dictionary attacks are not used very much any more
- Keystroke loggers and phishing beat any strong password
- If I watch (or listen!) to you type, I can get the full password regardless of complexity!
A: three, and the correct answer changes

- This is done with one-time passwords
- The answer is based either on the time, or the response to a changing challenge
- Usually requires hardware, or a piece of paper (but see below)
SecureID
SecureNet Key
SNK-004

- Why is this better?
- PIN does not travel through the computer or over the network, or reside in the server
- In fact, the issuer never knows the PIN!
- Easy server software
A login from my distant past

RISC/os (inet)

Authentication Server.

Id? ches
Enter response code for 70202: 04432234

Destination? cetus
$
Challenge/Response passwords

- Gets us out of the game
- Sniffing is not useful
- Man-in-the-middle can still be used
- Pretty much nothing to forget
- A PIN is helpful to make two-factor
- Surprisingly cheap
Why aren’t these ubiquitous?

- Cheap devices available before 1990
- People hate:
  - Having to carry the device
  - Entering the challenge (why SNK lost)
  - Entering the response
  - Carrying multiple devices
Further password criteria?

- Text-only is most general
- The web isn’t the only place we need these solutions
- But maybe iPhone-like interfaces will be ubiquitous enough
- Memorability? Shoulder-surfing?
Password Properties

- Memorable?
- Daily, monthly, yearly?
- Cost if forgotten
- Hardware needed?
- Training steps needed
- User selected?
- Single use?
- Changeable?
- Easy to write down?
- Easy to describe or transmit?
- Authentication speed
- Text, graphical, bio, other

Use Your Illusion (SOUPS 2008)

Please memorize the three distorted images shown above.
Some Whacko Ches Ideas

Passmaps
TODO: Find a point in New York State
Adirondacks are nice
Lakes have interesting shapes, let’s zoom in on the middle.
Upside down dog in the upper left
Dogs bark, check out the voice box
PW is lat/long of the center island
Passmaps?

- Reproducibly zoom in on a remembered set of map features?
- Lots of bits
- Maybe hard to shoulder surf
- Not challenge/response
- Memorable over a year?
- Nice for a touch screen?
Some Whacko Ches Ideas

How about passgraphs? Get Google out of the loop
Passgraphs?

• Similar to passmaps, but Google is out of the equation
• Maps can have a personal meaning
  • Is this a good thing, or a bad thing?
Some Whacko Ches Ideas

Obfuscated human-computed challenge response
Problem

• One-time passwords solve a lot of password problems

• One-time passwords (usually challenge/response) require something you have

• Equipment can be expensive, and it may be necessary to authenticate when equipment is not available
Baseball players

- Under a lot of stress
- Information is often vital to the game
- Not always the sharpest knife in the drawer
  - Babe Ruth forgot the signs five steps out on the field
Key insight?

• Humans can’t compute well, but perhaps they can obfuscate well enough
Proposed approach

• Use human-computed responses to computer challenges for authentication

• Though the computation is easy, much of the challenge and response is ignored

• Obfuscation and lack of samples complicate the attacker’s job beyond utility
Pass-authentication

- Literature goes back to 1967
- A variety of names used: reconstructed passwords, pass-algorithms, human-computer cryptography, HumanAut, secure human-computer identification, cognitive trapdoor games, human interactive proofs
Possible uses

• emergency holographic logins ("passwords of last resort")

• use from insecure terminals, when single session eavesdropping is probably not a problem

• if a solution is found: daily logins

• home run: online transactions: banking
Problems

- Can Joe Sixpack do this?
- Math is hard
- Procedural vs informational knowledge
Two Kinds of P-A Solutions

- ad hoc
- information theoretic
Ad Hoc solutions

- familiar to the designer
- idiosyncratic
- hard to analyze
Information theoretic

- Strong proof of work factor to crack
- None seem usable to me, and certainly not usable to Joe Sixpack
Current Threats and Some Revised Advice
Disclaimer

- These are all guidelines, suggestions, thoughts for your own risk/benefits analysis
- Every security person I’ve discussed this with has a somewhat different take
- Rethink and reengineer these systems, when appropriate
Threats to casual targets

- Password capture by phishing
- Password capture by keystroke logging
- Not dictionary attacks
- Most online systems limit password guessing
- Most attacks are wholesale, not targeted
Dictionary attacks still a concern

- For standard Unix logins
- For ssh password logins
- Against captured oracle streams, like PGP and ssh key files, cleartext challenge/response fields in protocols
- These are not mainstream attacks these days. Stolen laptops/iPhones a concern
Mother’s Maiden Name is a Bad Idea

• Secondary passwords are weaker, why would we use them?

• Mother’s maiden name is available on ancestor.com

• A hint about the primary password is much better!
Recommendations for users

• Use three levels of passwords based on importance:
  • No importance: NY Times, etc.
  • Inconvenient if stolen: Amazon
  • Major problem if abused: bank access, medical records(?)

• But these can change!
For users (cont.)

• Write down the rare ones if you must
• Don’t write down the password, write a reminder of the password
• Use variations to meet “strong” password requirements.
• Note required variations (i.e. lower case, no spaces)
Save your passwords with Firefox?

• Little difference against keystroke logging

• Key-ring protection mechanisms subject to dictionary attacks

• If stolen, you have given away an authentication factor
Updated Advice

For Implementors
Out of the Dictionary Attack Game Game

• Count and manage authentication attempts with a server

• pam_tally

• slow or block accounts (block is better than loss of control of an account)

• blacklist inquisitive IP addresses
Locking an account

- Locking or slowing account authentication simplifies denial-of-service attacks
- A locked account is much better than a stolen account
- Slower authentication, or a timeout on lockout, mitigates user support costs
Use an authentication server

- Centralizes the security function
- Make it strong and robust
- Replication is dangerous, reliability is better
- Limit authentication attempts
If password is forgotten

• Use a user-supplied reminder of the primary password

• Do not a (usually weaker) secondary password

• The net has ancestor, and personal data, and will have lots more soon

• Blacklisting doesn’t have to be forever
PIN != password

- A PIN is a sequence of digits only
- A password is a superset of PINs
- A passphrase is a series of words, but probably should not be called a *phrase*. *Passcode* is probably better
Identify the auth. server and pw rules

- Usually just an additional line to a web pages
- Yes, it leaks a little information
- It greatly eases the usability
  - name of server eliminates guessing and pw leakage
  - rules remind user of pw variation used
Don’t make acct. names too easy to guess

- Thwarts single password, multi-account scans
- U.S. Social security numbers are a little too guessable. Credit cards seem to be okay.
- But secret rules (hyphens in social security number?) reduce usability without improving security
Near-public authentication servers

- OpenID
- Openauth
- The general idea is appealing
Biometrics?

- Generally around 90% accurate
- A variety of workarounds
- Users may be reluctant to give up data
- Not bad for an auxiliary factor in strong authentication
Getting out of the game: ssh

- disable password logins. Use DSA key from a trustable client, that key locked with a strong pass-phrase
- two-factor authentication
- dictionary attack is rare endgame: you have to steal or own the client first
- Reasonably secure clients are doable
seismo.arpa.net login failures:

Strong Passwords, if you must
If you must, here are at least 60 random bits

- value part Peter sense some computer
- anxiety materials preparation sample experimental
- bliss rubbery uncial Irish
- 2e3059156c9e378
User choice is bad for entropy

- not user-chosen, but user can veto, waiting for a “good one”
- User-chosen phrases have much lower entropy
- they are going to write it down, for a while
- for daily use: who’s going to remember this over a year?
Uncial

uncial |'ən sh əl; -sēəl|  adjective

1 of or written in a majuscule script with rounded unjoined letters that is found in European manuscripts of the 4th–8th centuries and from which modern capital letters are derived.

2 rare of or relating to an inch or an ounce.

noun
an uncial letter or script.
Words are better than eye-of-newt

- much easier to type
- spelling checking (iPhone) is your friend, not enemy
Entropy >41 bits

Here is a list of ten random words chosen from a list of 1,020 iPhone-friendly English words. /dev/random is used to create the random numbers.

- firmly
- only
- signal
- merely
- behave
- proud
- shield
- pylori
- rounds
- harsh
Use Client certificates to limit attack surface

- Limiting connections to those with known client certificates gets you mostly out of the game
- Many mail clients do not offer client cert. processing, and should
Yeahbutfallal
Yeahbuttal

- These ideas will take time to deploy, if they do
- Huge installed base
- Corporate conglomerates have hundreds or thousands of these!
Who owns the app?

Who hosts it?

Third party applications? (401k, health, etc.)

Who developed it? (often long gone)

What is the business function

Buy-in is needed from all parties

Development costs?
Fix it anyway

• This is one of those economies of scale you told the shareholders the merger was going to give you

• Authentication servers should be relatively simple to code and maintain

• If you don’t understand who your users are, your security is shot from the start
Fix it anyway

- Annoyed users are uncooperative users
- There is a substantial cost when a large community has to deal with authentication foolishness on a routine basis
Strong Authentication, not strong passwords

• Use multi-factor authentication when it is really important

• Ubiquitous laptops and cell phones can be used for middle-level authentication
Selling weaker passwords

• ATM PINs of 4 digits work fine
• Cut user support costs
• Backup passwords are usually weaker
• Improve the users’ experience
• Annoyed users are less cooperative
• Tell them I said it was probably a good idea
Summary

- Distribute and require client certificates
- Use ssh with pass-phrased locked digital key, never passwords
- Use crypto services, like IMAPS, SMTPS
- Limit password attempts
People, we have to do better than this

• The Bad Guys are getting much better
• Our computer systems are getting much more important to us
• Security has to be thought about, and reviewed
There is plenty new to worry about

- Dangerous browsing
- Dangerous patches
- Dangerous COTS CPUS?
- Hidden malware
- The bad guys are pros, not disaffected teenagers
Dangerous browsing

- *All Your IFRAMES Point to Us*, Provos and Mavrommatis (Google), Rajab and Monrose (JHU); Usenix Security 2008
Dangerous patches

Provably-hidden malware

COTS CPUs dangerous?

Rethinking Passwords

Bill Cheswick
AT&T Labs - Research
ches@research.att.com
